Dear Splunk hiring team,

I am applying for the Principal Software Engineer role focused on search and analytics platform work. The role description matches how I have spent the last several years: building reliable analytics infrastructure, partnering across teams, and turning long-term technical goals into systems that hold up in production.

At Context Labs, I was Principal Software Engineer for a multi-tenant analytics platform used by distributed teams worldwide. I built the production data-service layer in Node.js and TypeScript (GraphQL) that integrated with Java APIs and PostgreSQL — the stable query and integration surface for reporting, dashboards, and operational use cases. I worked with product and analytics partners on data models and APIs, introduced reusable platform primitives, and improved observability practices that cut incident recovery time by 50%. I also mentored engineers and guided complex efforts from design through delivery across a globally distributed organization.

Before that at Filtered.ai, I led backend development of AWS and PostgreSQL pipelines for enterprise hiring assessments — ingestion, validation, scoring, and reporting with the reliability expectations enterprise customers require. Earlier roles at Turo, OneMarket, Tilt, and Yahoo reinforced the same themes: backend services at scale, dependable data flows, and cross-functional partnership when production behavior matters.

I have hands-on experience with distributed query infrastructure (Trino), SQL and PostgreSQL, AWS, and cloud-native platform patterns. I am drawn to Splunk because the work sits at the intersection of distributed systems, query execution, and platform evolution — problems where careful engineering, production learnings, and cross-org collaboration compound over time.

I would welcome the chance to discuss how my experience could contribute to Splunk's search platform and engineering culture.

Thank you for your consideration.

Sincerely,

David Marr
